Attention: Mr. Dan Gray

Subject: Revised Groundwater Monitoring Plan for Lena Road Class I Sanitary Landfill,
Manatee County, Florida

Gentlemen:

As requested and authorized by Mr. D. Gray, we submit this report on the revised groundwater monitoring plan for the subject sanitary landfill. It addresses the items referred to in the permit conditions pertaining to the revised plan and the assessment of the effectiveness of the landfill design.

This report has been prepared for the exclusive use of Manatee County Solid Waste Department for specific application to the subject project in accordance with generally accepted geotechnical and groundwater engineering practice. No other warranty, expressed or implied is made.

Please do not hesitate to contact us if you have questions, need additional information and/or when we can be of further assistance. We appreciate the opportunity to professionally serve you on this element of the project.

Very truly yours,

ARDAMAN & ASSOCIATES, INC.

Background

The Lena Road Landfill is located in east-central Manatee County within Sections 6 and 7 of Township 35 South, Range 19 East, Section 31 of Township 34 South, Range 19 East and Section 1 of Township 35 South, Range 18 East. The north boundary of the site is approximately State Road 64. The location of the subject landfill is superimposed on a USGS map in Figure 1.

The Lena Road Landfill consists of three stages. Stage I is the existing landfill area. Stage II is the landfill expansion area north of the existing landfill and Stage III is the Gun Club landfill area to the west of the Stage I area. No refuse is presently located within the Stage II area. Refuse from a presently inactive landfill is located within the Stage III area.

This revised groundwater monitoring plan (GWMP) deals with Florida Department of Environmental Regulation (FDER) Permits SO41-118353 (Stage I), SC41-095658 (Stage II) and SC41-095667 (Stage III). Figure 2 indicates our understanding of the existing monitoring well network for these three stages. The two SMR wells are located on Figure 1.

Between August 29, 1985 and September 22, 1989 a slurry wall system was installed around the three stages of the Lena Road Landfill. Stage I construction occurred between August 29, 1985 and November 14, 1985. Stage II construction was completed between June 20, 1989 and August 16, 1989 while the Stage III construction was completed between August 20, 1989 and September 22, 1989. A leachate collection system was installed as part of Stages I and III. The leachate collection system for Stage II will be installed at a later time before refuse is placed in this area.

A special condition of the permit requires a revised groundwater monitoring plan. This special condition also requires an assessment of the effectiveness of the existing landfill design and operation as it relates to the prevention of groundwater contamination. This report addresses both of the requirements.

A number of reports have been prepared by Ardaman & Associates, Inc. describing and discussing the geotechnical and groundwater conditions at the subject site. The data from the following reports form the basis for this revised GWMP:

- Geotechnical and Hydrogeological Investigation at the Existing Stage I Lena Road Landfill, Manatee County, Florida. January 26, 1983. File No. 82-7047.
- Geotechnical and Hydrogeological Investigation at the Existing and Proposed Expansion for the Lena Road Landfill, Manatee County, Florida. March 3, 1983. File No. 82-7047.

- Geotechnical/Groundwater Responses to letter dated April 18, 1983 from Mr. E. G. Snipes of FDER on Lena Road Landfill. May 27, 1983. File No. 82-7047.
- Additional Hydrogeological Investigation at the Lena Road Landfill, Manatee County. February 24, 1984. File No. 82-7047.
- Responses to FDER Questions, Construction Permit Application, Lena Road Landfill, Stage II, Manatee County, Florida. May 8, 1985. File No. 82-7047.
- Final Report for Laboratory Testing of Backfill Samples for Slurry Wall Construction at the Stage I Lena Road Landfill Site. December 9, 1985. File No. 82-7047A.
- Completion Report for Monitoring Wells Installed at Lena Road Landfill, Manatee County, Florida. March 10, 1989. File No. 86-115.
- Completion Report for Slurry Wall Construction Lena Road Landfill within Manatee County, Florida. October 10, 1989. File No. 86-115A.

In addition, Manatee County provided us with the water quality monitoring results for 1984 to 1989 from the existing monitoring well network.

Hydrogeological Setting

Based upon a review of the many Standard Penetration Test (SPT) borings performed within the subject site and along the route of the slurry wall, the near-surface subsurface profile generally consists of two generalized strata: a surficial fine sand to clayey fine sand layer overlying a relatively impervious stratum of clayey sand to clay (confining layer) which contains interbedded seams of silt and sand most prevalent between 50 to 150 feet below land surface. This clayey stratum begins about 15 feet below land surface and extends to the top of the Tampa Limestone unit approximately 335 feet below land surface. The artesian aquifer monitor wells on-site are open between 50 and 160 feet below land surface. The most transmissive zone within the top 150 feet of this clayey unit at the landfill site was approximately 125 to 150 feet below land surface. However, shallow domestic wells in the area are typically open between 50 and 150 feet below land surface. A generalized hydrostratigraphic section at the site is shown in Figure 3.

The surficial sandy soils generally consist of brown or gray fine sands to silty fine sands interbedded with gray clayey fine sands. The thickness of the surficial sandy soils is typically 10 to 15 feet.

The top of the confining unit consists of clay, silt or very clayey sand. According to the Unified Soil Classification System (USCS), the classification of fine-grained soils based on the plasticity of the soils, is clayey sands to highly plastic, inorganic clay or sandy clay. The coefficient of vertical permeability within the top part of the confining unit, as determined

from our laboratory permeability tests is on the order of 5×10^{-8} cm/sec.

The clayey unit beneath the top of this upper confining unit consists of clayey sands to clay with rock lenses to 335 feet below land surface.

The water table is approximately 13 feet above the potentiometric surface in the first artesian aquifer.

Water quality information from the monitoring wells are summarized in the Appendix.

Assessment of Existing Landfill Design

The upper part of the confining unit beneath the Lena Road Landfill consists of approximately 50 feet of alternating layers of highly plastic clay, slightly sandy to sandy clay, clayey to slightly clayey sand, and occasional lenses of silty fine sand. The predominant layer at the top of the confining unit is a green to gray clayey sand to clay with phosphate and it contains several facies. The major facies include:

- a) a gray and green to brown sandy clay to clay.
- b) a gray and green clayey sand.
- c) a gray dolosilt.

Based on the hydraulic characteristics of the upper confining unit at the landfill, the downward seepage rate is estimated to be on the order of 0.2 inches per year.

An assessment of the water quality changes after the installation of the slurry wall was determined by comparing the indicator parameters in the groundwater quality data for MW-2 and MW-3 wells. The indicator parameters include total dissolved solids, chloride, sodium, and total Kjeldahl nitrogen. The data are summarized in Figure 4. These wells are located at the edge of the slurry wall within the southwest corner of the Stage I fill area.

Both of these wells indicate a trend towards decreasing mineralization since the installation of the slurry wall system.

None of the other monitoring wells along the outside perimeter of the slurry wall indicate any temporal trend in groundwater quality characteristics. This is not unexpected because of the slow movement of the groundwater plume and because of the relatively low recharge rate in this area.

If the water level inside the wall is maintained 1 foot lower than the water level outside the wall, the total seepage of "fresh" groundwater into the leachate collection system is

0.3 acre-feet/year considering a 15-foot thick aquifer and 20,000 lineal feet of slurry wall along the perimeter of the fill areas. For the 314-acre landfill area, this is equivalent to an additional percolation volume of 0.01 inches/year. It is our opinion that, if this condition does exist, the amount of additional leachate which would have to be collected and treated would be quite insignificant compared to the amount of percolation through the final cover. Percolation through the final cover is expected to be no more than on the order of 2 inches/year after closure.

Revised Groundwater Monitoring Plan

The following revised groundwater monitoring plan shows the location of the monitoring wells, construction details of the monitor wells, and water sampling and chemical analysis protocol.

Well Locations

The proposed monitor well locations for the subject site are shown on Figure 5. The plan shows monitoring wells at 19 locations along the perimeter of the slurry wall system. This monitoring well network includes 19 surficial aquifer monitor wells, 7 artesian aquifer monitor wells and 17 piezometers. The surficial aquifer and artesian aquifer wells are existing while the piezometers are proposed.

Existing wells SMR-1 and SMR-2 (Figure 1) are proposed as the background wells. The piezometers are required for monitoring head differences across the slurry wall system. No data are available at this time to document head differences across the slurry wall. The piezometers will be located at the locations of surficial aquifer monitor wells. The piezometers are proposed to be located between the slurry wall and the leachate collection system.

The surficial aquifer wells adjacent to the slurry wall are considered "downgradient" wells only because they monitor water quality outside the slurry wall. These same wells will also be used to monitor water levels outside the wall so that during operation of the leachate collection system the water level within the slurry wall can be maintained below the adjacent groundwater level to the extent possible. In this context all of the surficial aquifer wells are "upgradient" wells, i.e., when the leachate collection system is operating as proposed, the surficial aquifer monitor wells will have higher water levels than the water level inside the slurry wall.

Piezometers are proposed between the slurry wall and the leachate collection system at the location of noted surficial aquifer wells. These piezometers will be shallow wells used to document the water level inside the slurry wall at each monitor well locations.

The length of the collection zones for the piezometers will be 5 feet. The collection zone will be located below the seasonal high water table elevation.

Existing wells not used for monitoring will be properly abandoned and upon completion a report will be provided to the FDER documenting abandonment procedures and well locations. CW-3 well in the Stage III area is such a well.

Well Construction

The surficial aquifer wells including the piezometers will be constructed in the following manner after being permitted by the Southwest Florida Water Management District (SWFWMD).

A schematic of the monitor well construction is presented in Figure 6. The 2-inch diameter wells will be fully screened in the collection zone and be installed by advancing a 6-inch diameter hole to the final well depth, inserting a length of 2-inch diameter No. 10 slotted PVC pipe connected to a 2-inch diameter schedule 40 PVC riser, backfilling with a clayey sand to land surface. The monitor wells will be protected by a lockable vented cap.

Based on our knowledge of the site geology, the piezometers will typically vary in depth from 10 to 20 feet.

The following pertinent hydrogeological data will be documented for each monitor well:

- Well identification
- Latitude/Longitude of well
- Aquifer monitored
- Casing diameter
- Casing type and length
- Elevation at top of pipe
- Elevation at land surface
- Elevation of top and bottom of collection zone
- Total depth of well
- Screen type and slot size
- Lithologic description of the screened zone
- Permeability of screened zone
- Direction of groundwater flow in screened zone
- SWFWMD or County well construction permit number

Sampling Protocol

Each well would be sampled quarterly. Grab samples will be taken using a peristaltic, submersible or bladder pump or bailer. The procedures for sampling are summarized as follows:

- Transport the sample bottles and preservatives to the site as provided by the water analysis laboratory.
- Rinse, with distilled water, the tubing or sampling device to be used for sample collection to avoid cross contamination.
- Measure in situ water level to the nearest .01 foot from the top of the casing.

Purge the well of a minimum of three casing volumes prior to sampling. (A casing volume is determined by subtracting the water table depth from the depth of the well then calculating the volume within that length of casing). Record water temperature, pH and electrical conductivity of the pumped water at the start of pumping and every five minutes thereafter. Guidelines for obtaining water level measurements are provided in Table 1.

- Withdraw water sample and place into proper container once measurement values from three consecutive readings are constant. Laboratory instructions (e.g., type of bottle, quantity of sample, and preservative) must be followed carefully and thoroughly. Record types of materials that the water sample contacted during collection (e.g., teflon, pvc, steel).
- Label sample bottle with well identification(s), final temperature, pH, conductivity, date and sampler's initials.
- Ice samples down and prepare for transportation to water analysis laboratory.
- Complete field note-taking as per water sample log sheet shown in Table 2. Document the pump operating time prior to collection of sample plus pumping rate at well in gallons per minute. Alternatively, document the casing volumes evacuated from the well prior to sampling.
- Transmit collected samples to water analysis laboratory within 24 hours of sampling. The chain of custody form to be used is shown in Table 3.

Sample, collection, preparation and testing procedures will adhere to the applicable procedures set forth by the Florida Department of Environmental Regulation.

Groundwater Monitoring Parameters

The groundwater monitoring parameters will adhere to the lists from the appropriate FDER permit conditions.

At a minimum, analyses for the following indicator parameters will be determined quarterly for each of the monitor wells and submitted to the FDER on a timely basis. Water level data will be obtained on all piezometers quarterly.

Field Determinations

- Water Level
- Temperature
- pH
- Specific conductance

Laboratory Determinations

- Total Dissolved Solids
- Total Organic Carbon
- Total Kjeldahl Nitrogen
- Chloride
- Iron
- Bicarbonate

It has been our experience that these parameters are most likely to be elevated above background levels in a leachate plume from a sanitary landfill. If the results of the routine monitoring of indicator parameters from any of the wells indicate the presence of leachate, then a more elaborate analysis program will need to be established with FDER during the next quarterly sampling. If the results of the analyses for the added parameters do not exceed the MCL, then these added parameters will be analyzed on an annual basis until the indicator parameters have concentration levels lower than determined in the initial sampling. Added parameters above the MCL will be monitored on a quarterly basis.

Analyses for metals will be performed on unfiltered samples. However, because of the possibility that the preserved metals sample may contain suspended particulates, any metal analysis which indicates non-compliance with the applicable groundwater standard will be considered as potentially unrepresentative of the actual groundwater. Consequently, both filtered and unfiltered samples will be obtained from the subject well on the next scheduled sampling trip and both of the samples will be analyzed for metals. Procedures for in-line field filtering will be those approved by FDER. The analytical test result sheets to FDER on unfiltered samples for metals will contain the following type note: "The results reported herein for metals were performed on unfiltered groundwater samples. These results may not be representative of the actual groundwater quality".

Proposed Action

The groundwater monitoring plan will be implemented with 90 days after approval by the FDER. After four quarters of data are available the data collection network and monitoring parameters should be reviewed. Mean sea level elevations need to be obtained for all piezometers and wells in the network. Water level elevations should be reported in addition to depths below land surface.
